I am just starting to read Lee's "Riemannian Manifolds" and one of the first exercises in the text (2.7) is the following: given a smooth map $f: (M, g) \rightarrow (N, \bar{g})$, prove that f is a local isometry iff $f^* \bar{g} = g$.

The book assumes working knowledge of smooth manifolds and Lie brackets, while many students need review of the former, and know nothing of the latter. Lee doesn't give enough examples beyond constant curvature spaces: there is virtually no mention of warped products, Riemannian submersions, Lie groups, or homogeneous spaces.

PROBLEMS; "RIEMANNIAN GEOMETRY" 3 Problem 6. [Open submanifolds] Let M be a C^∞ manifold and let U be an open subset of M . (a). Prove that U inherits from M a natural structure of a (not necessarily connected) C^∞ manifold. This C^∞ manifold is called an open submanifold of M . (b). Prove that the inclusion map $i: U \rightarrow M$ is a C^∞ map. (c).

In this paper, we study the curvature properties of a manifold with structure group G_2 whose fundamental 3-form is deformed by a Killing vector field of unit length. We obtain some results concerning conditions under which this manifold is flat, Einstein, or isometric to the unit sphere.

to my earlier book on topological manifolds [Lee00]. This subject is often called differential geometry. I have mostly avoided this term, however, because it applies more properly to the study of smooth manifolds endowed with some extra structure, such as a Riemannian metric, a symplectic structure, a Lie group structure, or a foliation, and of the
